

FREE STARTER PACK · HOLO · CLAUDE CODE + MEDIAPIPE

The Bare-Hands *Holo* Pack

Control your notes with your bare hands, through your webcam. Pinch cards out of the air and throw them with real momentum. Grab a real Smithsonian scan of the Apollo 11 capsule and pull it apart with two hands. Press one key and it all goes gold while an AI voice narrates what your hands do. No cloud, no API keys, no accounts — everything runs on your machine.

Run it in two minutes

What you need: Python 3 (already on every Mac; python.org for Windows) and Google Chrome. That is the whole list — the hand tracking ships inside the folder, so it works offline and ad-blockers cannot break it.

1. Unzip the folder anywhere
2. Open a terminal in that folder and run:

```
python3 server.py
```
3. Open Chrome at: `http://localhost:4890`
4. Allow the camera. Raise a hand.

1 Camera blocked?

Click the camera icon at the right end of Chrome's address bar, choose Allow, then hit RETRY CAMERA on the page. On a Mac also check System Settings > Privacy & Security > Camera > Chrome.

2 Light your hands.

A lamp facing you beats any setting in the code. Every webcam hand tracker on earth works better with bright, even light, and this one is no exception.

3 Port already in use?

Run it somewhere else: `HOLO_PORT=4891 python3 server.py` — then open `localhost:4891`.

4 Acting strange after hours of uptime?

Stop the server (Ctrl+C) and start it again. Long-lived local servers on macOS can quietly lose file access; a restart fixes it in five seconds.

5 No camera handy?

Add `?sim=1` to the URL and a scripted pair of synthetic hands plays a demo loop. The mouse also works everywhere as a fallback.

Your hands are the interface

Best for: learning the whole vocabulary in one sitting. An on-screen legend shows all of it while you play.

A pinch means your thumb and finger actually touch. Near-misses are ignored on purpose — that is what keeps the deck from firing while you gesture at the camera.

Pinch a card

Grab it. Drag it. Let go while moving and it flies with real momentum.

Quick pinch (a tap)

A folder orb fans out its files. A note opens in the reader. Tap the orb again to close the fan.

Flick off-screen

Throw a note hard enough to leave the screen and it evaporates. Reopen its orb to bring it back.

Two pinches, apart / together

Zoom the whole scene. Twist both hands to rotate it.

Two-hand stretch on a held card

Pull it big to open the reader. Crush it small and the voice reads you the gist.

Peace sign, held

The reset. Everything returns to its original place and size — a page refresh without the refresh.

Drag to the right edge

Dock a card on the shelf to keep it handy.

EFFECTS (press F) adds the showy ones: **palm hold** = repulsor blast · **open palm then fist** = force-pull · **point one finger** = draw glowing ink · **clap** = reset · **both palms sweep down** = tidy into a grid. They listen continuously, so they are livelier on camera and twitchier at a desk. Off for work, on for filming.

Make it yours: if you remember one gesture, remember the held peace sign. It undoes any mess, including a board you have thrown into chaos on purpose.

Museum pieces, in your hands

Best for: the moment you show a friend. Two real Smithsonian scans ship in the box, both public domain.

APOLLO 11 COMMAND MODULE — the actual scan of Columbia, scorch marks and all.

TRICERATOPS — a real fossil skeleton.

Grab a model and twist your wrist while pinching — it spins with inertia. Stretch it bigger with two hands and it **comes apart**: the closer you zoom, the further its pieces separate. Shrink it and it fuses back together. Single-mesh scans are automatically sliced into shards at load, so everything opens up, not only models that happen to arrive in parts.

Any model you download becomes a prop. Drop a **.glb** file into the props folder and refresh:

```
holo-gestures-free/  
  props/  
    apollo-11-module.glb  
    triceratops.glb  
    your-model-here.glb      <- any .glb shows up on the deck  
  
# If a downloaded model refuses to load it is usually Draco-compressed.  
# Decompress it once and it will work:  
npx @gltf-transform/cli copy in.glb out.glb
```

Make it yours: Sketchfab, the Smithsonian's 3d.si.edu, and Poly Pizza have thousands of free .glb downloads — skulls, engines, sneakers, planets, spacecraft. Check each model's license before using it in anything you sell.

Point it at your own brain

Best for: turning the demo into a tool. It ships with sample notes so it works instantly; one line points it at your real ones.

Edit **holo.json** in the folder and set the path to any folder of markdown files. Subfolders become orbs; files become the cards you pinch out of the air:

```
{"folder": "/path/to/your/notes"}
```

Then press **J** — Jarvis mode. The deck goes gold and a voice speaks about what your hands do: file a card on the shelf and he says so; crush a note between your hands and he reads you the gist. The voice is your computer's own local speech engine. No account, no key, no setup.

Privacy, in one sentence: the hand tracking runs entirely on this page, on your machine — camera frames never leave your computer, and the tracking libraries are shipped inside the folder rather than fetched from the internet.

Make it yours: the whole thing is one readable HTML file plus a small Python server, MIT licensed. Open holo.html and every gesture threshold is a named constant near the top.

PROMPT 01 · ADD YOUR OWN MODEL

Put anything in your hands

Best for: a skull, an engine, your own product — anything you can find or export as .glb.

Open the HOLO folder in Claude Code and paste this:

I dropped a new model at props/MY-MODEL.glb and I want it on the deck.

1. Confirm the server lists it at /api/props.
2. If it fails to load, check whether it is Draco-compressed (extensionsRequired in the GLB header). If it is, decompress it with `npx @gltf-transform/cli` copy and replace the file.
3. In `holo.html` find the POSE map inside `loadProps` and add an entry for my file so it faces the viewer at a sensible size, for example:
`'MY-MODEL.glb': { rx: .15, ry: 0, scale: 1 }`
4. Reload and tell me the rotation and scale numbers you chose and why.
5. Run `http://localhost:4890/?probe=1` and confirm the title says 26/26.

Make it yours: **rx** tilts the model, **ry** turns it, and **scale** resizes it. Long models like skeletons usually want a scale near 2; compact objects look right at 1.

PROMPT 02 · RETUNE THE FEEL

Make it fit your hands

Best for: pinches that feel too fussy, or a deck that reacts too eagerly.

In `holo.html`, near the top of the script, are the gesture constants: `PINCH_IN`, `PINCH_OUT`, `PINCH_EARN` and `AMP`.

My pinch does not register reliably. Raise `PINCH_IN` a little (a larger number is more forgiving), keep `PINCH_EARN` so a flicker cannot fire a pinch, and explain what each number does in one line. Then run `?probe=1` and confirm 26/26 before telling me you are done.

Make it yours: **AMP** is the reach multiplier — raise it if you have to stretch your arm to touch the edges of the screen, lower it if the cursor feels twitchy.

PROMPT 03 · INVENT A GESTURE

Teach it a new move

Best for: making the deck yours in the most literal way. This is the fun one.

In `holo.html`, `handMetrics()` turns hand landmarks into simple measures (pinch, open, openish, fist, point, peace) and the gesture logic reads those every frame.

Add a THUMBS UP gesture: thumb extended, the other four fingers curled. When I hold it for about half a second, dock the card nearest my hand on the shelf and speak a short line in Jarvis mode.

Rules I care about:

- Fire on a HELD pose, not a fast motion. Motions are unreliable on a webcam.
- Put it behind the EFFECTS toggle with the other always-listening gestures.
- Add a line to the on-screen legend so I can see it exists.
- Add a test to the `?probe=1` battery that drives synthetic hands and proves it fires, then show me the battery passing at two window sizes.

Make it yours: the reason to prefer a held pose is written into this build the hard way — every motion-based gesture here was eventually replaced by a static one because cameras read poses far more reliably than movements.

PROMPT 04 · REBRAND IT

Your name on the glass

Best for: showing clients, or shipping your own version to your own audience.

In `holo.html`, change the branding so this deck is mine:

- The title top-left and the ring label (currently H0L0 and H.0.L.0.).
- The accent colour used across the orbs, cards and legend.
- In Jarvis mode, the spoken lines live in a small object of phrases.
Rewrite them in my voice: dry, short, a little funny.

Keep the layout and gesture behaviour exactly as it is, show me a before-and-after screenshot, and confirm `?probe=1` still passes 26/26.

Make it yours: ask for the accent colour as a single constant if it is not already — then every future re-skin is one line instead of twenty.

This deck is the free slice

HOLO is the hands. The full build is **JARVIS** — an AI second brain that runs on these same bare-hand controls and then keeps going: a 3D galaxy of every note you own that you steer by hand, a voice you talk to that answers from your notes and flies the camera to its sources, real phone calls it makes on your behalf, email and calendar, a computer-takeover mode that drives your mouse while narrating what it is doing — and eyes: it can see you, greet you when you sit down, and tell you to fix your posture with a straight face.

Every piece was built live with Claude Code, and the AI Workshop community gets the builds, the install lessons, and the method behind them — so you can build and sell your own.

Upgrade to the full Jarvis

The AI Workshop (paid community) has the complete JARVIS second brain, every install lesson, all the skill packs, and a room full of builders shipping AI tools for real businesses.
